

TrendTrade101 fixed baseline report

Completed original25 daily FULL hypothetical pilot

The US account returned **-3.98%** after fees and tax; the Japan account returned **+0.79%**. Both ended entirely in cash. These are assumption-based simulation results, not independently verified historical execution or evidence of future profitability.

Scored interval: 1 November 2024 through 31 August 2026, inclusive. The endpoint 1 September 2026 is excluded. All returns below are total period returns, not annualized.

Account result	US account	Japan account
Currency	USD	JPY
Initial equity	100,000.00	16,000,000.00
Final equity and cash	96,016.43	16,125,982.89
Gross period return	-3.41%	+1.26%
After fee period return	-3.98%	+1.26%
After tax period return	-3.98%	+0.79%
Maximum drawdown	4.19%	1.90%
Closed aggregate trades	13	10
Win rate after fees	15.38%	60.00%
Fees	572.00	0.00
Net simulated tax	0.00	75,917.17

After-tax equity includes unrealized holdings at causal marks. Gross and after-fee views add back costs along the same realized after-tax trading path; they are not separately reinvested simulations. The chart ends at the excluded September boundary without using September prices.

Universe and account configuration

The fixed membership is the original25 basket: 12 US-listed symbols and 13 Japan-listed symbols. The two accounts are independent, long-only, unlevered and denominated in their local currencies. Cash earns no modeled interest. There is no FX conversion or combined cross-currency return.

All original25 members

US 12: NVDA, AVGO, AMD, MU, TSM, ASML, LRCX, ANET, VRT, MSFT, GOOGL, ORCL

Japan 13: 6857.T, 8035.T, 6146.T, 6920.T, 285A.T, 4062.T, 4004.T, 4186.T, 4063.T, 5803.T, 5801.T, 9984.T, 2737.T

Observation and scoring boundaries

Coverage group	Observed input window	Warmup bars	Scored bars
US all 12	2024-10-02 to 2026-08-31	22 each	457 each
Japan except 285A.T	2024-10-02 to 2026-08-31	21 each	445 each
Japan 285A.T Kioxia	2024-12-18 to 2026-08-31	0	413

Warmup is exactly the available 2-31 October 2024 observations for already listed members. It initializes indicators and signal history only: no prestart trades, carried positions or P&L. Kioxia starts with its actual post-listing cached observations on 18 December 2024 and becomes eligible only as its indicators become defined. No shared extra burn-in gate is applied.

Dates follow each market calendar. Only valid observed completed bars advance indicator state; missing bars or fill quotes are not fabricated. The retained input contains 479 US bars per member, 466 Japan bars per established member, and 413 Kioxia bars, including warmup. September 2026 and later price observations are excluded before numerical replay.

Active fixed allocation settings

Setting	US	Japan
Initial cash and aggregate market-value cap	USD 100,000	JPY 16,000,000
Target notional per entry	USD 100,000 / 15 = 6,666.666666...	JPY 16,000,000 / 15 = 1,066,666.666666...
Assumed order unit	1 share	100 shares
Fee per buy or sell	min(notional x 0.00495, USD 22)	JPY 0
Spread and slippage	0 bps / 0 bps	0 bps / 0 bps

Every entry uses the fixed initial-capital fraction 1/15, regardless of current equity or ADX magnitude. Filled notional can be smaller because of whole units, cash, reservations or the aggregate cap. Price stops and price targets are disabled; their thresholds are null.

Retained values that are inactive in this pilot

Minute delay 20, minute entry cutoff 63 and minute continuous-bar flattening are stored inherited settings only. Daily trading uses next-session Open and monthly Open liquidation. ADX allocation base USD 10,000, Japan base null, and position scale 1 are inactive because allocation is fixed; no ADX-weighted allocation was run. The ADX > 25 signal filter remains active.

Indicators and complete signal rules

Active indicator or rule	Runtime value
Moving averages	SMA fast 5 and SMA slow 20, using completed Close
MACD and signal	EMA 12 minus EMA 26; signal EMA 9 of defined MACD
Histogram H	MACD minus signal, with no factor of 2
ADX	Wilder ADX 14; entry requires strict $ADX > 25$
Cross lookback	5 completed valid bars, including the current bar
Histogram entry increments	3 strictly positive increments across 4 defined H values
Histogram exit drawdown	40% from the current positive-hump peak; equality triggers

Causal initialization

Each EMA starts at the arithmetic mean of its first N valid observations and then updates with $\alpha = 2/(N+1)$. MACD becomes defined after 26 observations; its nine-value signal and histogram first become defined at observation 34. ADX uses Wilder means over 14 transitions, then 14 defined DX observations; its first value occurs at observation 28. No undefined value is filled backward.

Price-dimensional indicator state and histogram history are rescaled at the effective split time. Startup can observe an already-positive histogram hump without its earlier nonpositive boundary. This is retained as a disclosed diagnostic; it is not silently filled with older unobserved history.

FULL entry requires every condition

1. A bullish SMA5/SMA20 cross and a bullish MACD/signal cross have both occurred within the inclusive last five completed valid bars. A cross requires previous fast $\leq$ slow and current fast $>$ slow. The two crosses need not occur on the same bar.
2. The last four defined histogram values satisfy $H[t-3] < H[t-2] < H[t-1] < H[t]$, and the final $H[t]$ is strictly positive.
3. ADX(14) is defined and strictly greater than 25. Each distinct pair of SMA and MACD cross identities can generate an entry signal only once. Repeated daily matches do not resubmit the same pair.

SMA5 slope is $100 \times (SMA5[t] / SMA5[t-1] - 1)$. It determines competing buy-order priority only; a positive slope is not an additional entry condition. An eligible signal still has to pass the account, lot and trading-time rules.

Histogram and scheduled exits

Track the maximum H reached during the current positive hump. Exit the entire held ticker position when H is declining and $H \leq 60\%$ of that peak, or whenever defined H is nonpositive. Evaluate the exit before resetting the positive-hump state at $H \leq 0$. Undefined histogram values do not trigger a histogram exit.

Histogram exits are ordinary next-observed-session Open orders. Separately, all holdings are scheduled for liquidation at the calendar-planned Open on each month's last trading day. Buying is prohibited for that entire trading day. There is no intraday price stop, take-profit rule or implied end-of-window liquidation.

Execution ledger costs and valuation

Daily order timing and priority

A completed signal bar can only generate an ordinary order for an observed tradable Open strictly later than its Close. The completed signal bar's own Open cannot fill that order. The daily path does not apply the retained 20-minute delay or 63-minute entry cutoff. Calendar-planned month-end exits are due at the last trading day's Open, with a full-day buy ban.

Sells precede buys. Competing buys are ordered by descending signal-time SMA5 slope, then ticker, then event ID. Exit orders aggregate the whole held ticker position and cancel its queued buys; a ticker sold at an instant is not bought back at that same instant. Distinct eligible entries may add to the same held ticker position within account limits.

Reservation and sizing mechanics

At signal time, available cash excludes existing cash reservations. Aggregate cap room is the initial market-value cap less held exposure and queued notional reservations. The prospective notional is the smallest of the fixed target, cap room and cash-affordable notional. Reserve this notional plus its estimated fee, and determine an integer number of assumed trading units using the signal price.

At fill time, use only an Open observed at that instant, recheck cash and current market-value capacity, and round down to whole units. Quantity may shrink but may not grow above the signal-time queued quantity. No borrowing, fractional purchases or assumed fills at stale prices are allowed. Missing fill quotes leave the order pending and flagged; the replay does not manufacture liquidation at its endpoint.

Costs and current year tax

US commission is $\min(\text{traded notional} \times 0.00495, \text{USD } 22)$ on each buy and each sell. Japan fees are zero under the approved simulation assumption. Spread and slippage are both zero. Dividend cash and FX effects are excluded. Fees, tax and equity use floating-point arithmetic without an additional currency-rounding rule; this report rounds display values only.

Tax is accrued at realization at 20.315% of the positive net realized after-fee profit for the current local calendar year. A later realized loss can refund that year's prior accrual. A loss in one year cannot offset a different year; unrealized P&L is not taxed.

Realized year	US after-fee P&L	US tax	Japan after-fee P&L	Japan tax
2024	-221.82	0.00	-171,800.00	0.00
2025	-2,924.08	0.00	290,000.05	58,913.51
2026	-837.67	0.00	83,700.00	17,003.65

Fresh accounts and causal marks

This pilot begins with fresh initial cash and zero positions. Prior history warms indicators only. It does not continue an ordinary out-of-sample ledger. The retained broader policy is fresh accounts for training, final baseline and final selected runs; ordinary out-of-sample accounts are continuous. Those other runs were not performed here.

Equity is cash plus marked holdings. Observed Open, completed Close and scheduled events are processed in causal order; completed-Close valuation is preserved before a same-instant Open can replace a mark. Missing valuation quotes retain the last-known mark with a flag. Maximum drawdown uses the after-tax marked equity series, including unrealized holdings.

Price assumptions and result diagnostics

PA01 Price basis. Cached OHLC is assumed to be split-adjusted only through its original retrieval. Reconstruct historical unadjusted OHLC by multiplying each earlier quote by the product of recorded split ratios effective after that quote and no later than original retrieval. Dividend cash is excluded; no total-return adjustment is inferred.

PA02 Split completeness. Recorded splits are assumed sufficient for this hypothetical reconstruction. Later recorded split factors may reverse the snapshot normalization of earlier prices, but later price values never enter signals, fills, valuation or returns. At a modeled split, held quantity multiplies by the ratio, cost per share divides by it and total cost is preserved; marks and price-dimensional indicator state rescale consistently. Unsupported special actions, conflicting split records and unsupported fractional or odd-lot entitlements block affected execution.

PA03 Trading units. US whole shares and Japan 100-share units are approved simulation assumptions, not independently certified historical lot evidence. **PA04 Identity.** Cached ticker-to-issuer continuity is retained; no frozen member is removed. Known contradictory or unsupported events still block affected runs. None of these assumptions has been independently verified.

Trading and exposure diagnostic	US	Japan
Average trade after-fee return	-4.71%	+1.72%
Mean holding time in calendar days	8.0	5.6
Calendar-time-weighted capital use	1.03%	0.46%
Maximum capital utilization	14.23%	8.69%
Maximum single position equity share	7.37%	8.69%
Maximum position HHI	1.00	1.00
Below-lot orders	0	13
Canceled orders	1	0
Positive H without known prior boundary bars	42	21
Undefined histogram bars in scoring window	132	177
Histogram exits / monthly Open exits	12 / 1	6 / 4

Both accounts: zero residual positions and ending exposure; zero missing-price orders, end-unfilled orders, cash-shortfall orders, position-cap-shortfall orders, unsuccessful scheduled liquidations and zero-volume observations. The engine's sparse flag is false in each account. Capital utilization is exposure/equity weighted by calendar elapsed time, including nontrading periods. A maximum position HHI of 1.00 means held exposure can be concentrated in one ticker even when most account capital is cash.

What this completed pilot can establish

Trading was infrequent and average capital utilization was low. Japan's 13 below-lot orders show that a fixed target often cannot buy a full 100-share unit. This short-history, retrospectively chosen original25 basket is subject to universe selection and survivorship bias. Quote Opens are execution proxies and fill eligibility does not rely on eventual bar volume. Vendor coverage, auctions, corporate actions, IPO history and historical units still require independent audit.

No parameter tuning, optimization, ADX-weighted comparison, formal holdout evaluation or five-year/full-market validation is included. The September 2026 onward protected price period remains excluded. Software and accounting verification establish reproducibility under the stated assumptions; they do not certify those assumptions or turn this result into a performance forecast.

Verification and reproducibility identifiers

130 software tests passed. The pinned plain-text code review cleared after two split-input guards were strengthened. A fresh reviewed replay reproduced all preliminary account events and metrics exactly. Independent checks reconciled the result. Original pending input-review statuses were retained, and no assumption was promoted to independently verified evidence.

Canonical configuration v0.16 governs this run. Its Sections 3-13 are byte-identical to v0.15; v0.16 adds explicit hypothetical authorization. Execution used the exact base snapshot plus reviewed hypothesis-mode source changes. The base commit alone is not claimed to identify the final executed source. The modified-file hashes below complete that source description.
